Summary
ENS0 Alert System Status: El Niño Watch

ENS0-neutral conditions continue.*

Positive equatorial sea surface temperature (SST) anomalies continue across the Pacific Ocean.

There is a 58% chance of El Niño during the Northern Hemisphere winter, which is favored to last into the Northern Hemisphere spring 2015.*

* Note: These statements are updated once a month in association with the ENSO Diagnostics Discussion, which can be found by clicking here.
From January-February 2014, SSTs were mostly below average across the eastern equatorial Pacific.

From March-June 2014, above-average SSTs (departures >0.5°C) were evident near the Date Line and in the eastern Pacific.

Recently, positive SST anomalies cover the equatorial Pacific.
Niño Region SST Departures (°C) Recent Evolution

The latest weekly SST departures are:

- Niño 4: 0.9°C
- Niño 3.4: 1.0°C
- Niño 3: 0.9°C
- Niño 1+2: 0.4°C
SST Departures (°C) in the Tropical Pacific During the Last Four Weeks

During the last four weeks, equatorial SSTs were above average across the Pacific.
During the last four weeks, equatorial SSTs were above-average across the Pacific and western Indian Ocean, and below-average north of Australia (the Maritime Continent) and in the eastern Atlantic Ocean.
During the last four weeks, positive SST anomalies persisted in the equatorial Pacific.
During the last four weeks, changes in equatorial SST anomalies were small across most of the equatorial Pacific.
Upper-Ocean Conditions in the Equatorial Pacific

The basin-wide equatorial upper ocean (0-300 m) heat content is greatest prior to and during the early stages of a Pacific warm (El Niño) episode (compare top 2 panels), and least prior to and during the early stages of a cold (La Niña) episode.

The slope of the oceanic thermocline is least (greatest) during warm (cold) episodes.

Recent values of the upper-ocean heat anomalies (near zero) and thermocline slope index (near zero) reflect ENSO-neutral conditions.

*The monthly thermocline slope index represents the difference in anomalous depth of the 20°C isotherm between the western Pacific (160°E-150°W) and the eastern Pacific (90°-140°W).*
Subsurface temperature anomalies strongly increased during January - March 2014. During April-July 2014, the positive anomalies decreased to near zero. Temperature anomalies increased between late July and late August, were relatively unchanged during September-October, and increased during November.
Sub-Surface Temperature Departures in the Equatorial Pacific

Since mid September, positive subsurface temperature anomalies have stretched across most of the equatorial Pacific.

Recently, positive subsurface anomalies in the central Pacific are expanding eastward and strengthening.
Tropical OLR and Wind Anomalies During the Last 30 Days

Positive OLR anomalies (suppressed convection and precipitation, red shading) were evident over Indonesia and near the Date Line. Negative OLR anomalies (enhanced convection and precipitation, blue shading) were apparent east of the Philippines.

Low-level (850-hPa) winds were near-average across most of the equatorial Pacific. Weak westerly wind anomalies were observed near 140°W-120°W and weak easterly wind anomalies were evident in the far western Pacific.

Anomalous upper-level (200-hPa) easterly winds were evident across much of the central and eastern equatorial Pacific.
Intraseasonal variability in the atmosphere (wind and pressure), which is often related to the Madden-Julian Oscillation (MJO), can significantly impact surface and subsurface conditions across the Pacific Ocean.

Related to this activity:

Significant weakening of the low-level easterly winds usually initiates an eastward-propagating oceanic Kelvin wave.
Weekly Heat Content Evolution in the Equatorial Pacific

During January - May 2014, the downwelling phase of a strong Kelvin wave crossed the Pacific.

During May-July, positive temperature anomalies progressively disappeared from the equatorial Pacific in response to the upwelling phase of the Kelvin wave.

Since early October, positive subsurface temperature anomalies have expanded eastward and strengthened.

Oceanic Kelvin waves have alternating warm and cold phases. The warm phase is indicated by dashed lines. Down-welling and warming occur in the leading portion of a Kelvin wave, and up-welling and cooling occur in the trailing portion.
Recently, winds have become closer to average over the equatorial Pacific.

Westerly Wind Anomalies (orange/red shading)
Easterly Wind Anomalies (blue shading)
Upper-level (200-hPa) Velocity Potential Anomalies

During June-July 2014, and mid August- mid September, eastward propagating velocity potential anomalies were observed.

Recently, the Madden Julian Oscillation (MJO) emerged and can be observed in the eastward propagation of anomalies.

Unfavorable for precipitation (brown shading) Favorable for precipitation (green shading)
From May through early July, weak negative anomalies persisted over the western equatorial Pacific.

During late July-early August 2014, positive OLR anomalies shifted eastward from the Indian Ocean, across Indonesia to near the Date Line.

During September and October, positive anomalies persisted over Indonesia.

During November, positive anomalies have been observed near the Date Line and western Pacific.

Drier-than-average Conditions (orange/red shading)
Wetter-than-average Conditions (blue shading)
Oceanic Niño Index (ONI)

The ONI is based on SST departures from average in the Niño 3.4 region, and is a principal measure for monitoring, assessing, and predicting ENSO.

Defined as the three-month running-mean SST departures in the Niño 3.4 region. Departures are based on a set of improved homogeneous historical SST analyses (Extended Reconstructed SST - ERSST.v3b). The SST reconstruction methodology is described in Smith et al., 2008, J. Climate, vol. 21, 2283-2296.)

Used to place current events into a historical perspective

NOAA’s operational definitions of El Niño and La Niña are keyed to the ONI index.
NOAA Operational Definitions for El Niño and La Niña

El Niño: characterized by a positive ONI greater than or equal to +0.5°C.

La Niña: characterized by a negative ONI less than or equal to -0.5°C.

By historical standards, to be classified as a full-fledged El Niño or La Niña episode, these thresholds must be exceeded for a period of at least 5 consecutive overlapping 3-month seasons.

CPC considers El Niño or La Niña conditions to occur when the monthly Niño3.4 OISST departures meet or exceed +/- 0.5°C along with consistent atmospheric features. These anomalies must also be forecasted to persist for 3 consecutive months.
ONI (°C): Evolution since 1950

The most recent ONI value (August - October 2014) is 0.2°C.
Historical El Niño and La Niña Episodes Based on the ONI computed using ERSST.v3b

NOTE (Mar. 2012): The historical values of the ONI have slightly changed due to an update in the climatology. Please click [here](#) for more details on the methodology.
## Historical El Niño and La Niña Episodes Based on the ONI computed using ERSST.v3b

Recent Pacific warm (red) and cold (blue) episodes based on a threshold of +/- 0.5 ºC for the Oceanic Niño Index (ONI) [3 month running mean of ERSST.v3b SST anomalies in the Nino 3.4 region (5N-5S, 120-170W)]. For historical purposes El Niño and La Niña episodes are defined when the threshold is met for a minimum of 5 consecutive over-lapping seasons. The complete table going back to DJF 1950 can be found [here](#).

</table>
The chance of El Niño is 58% during the Northern Hemisphere winter and decreases into spring/summer 2015.
Most models favor El Niño (greater than or equal to +0.5°C) to develop during November 2014 - January 2015 and to persist through Northern Hemisphere spring 2015.
The CFS.v2 ensemble mean (black dashed line) predicts El Niño into mid 2015.
Atmospheric anomalies over the North Pacific and North America During the Last 60 Days

During late September- late November, the pattern generally featured an anomalous ridge over western N. America and an anomalous trough over eastern N. America. This pattern led to above-average temperatures in the West, and below average temperatures in the East.

Summary

ENSO Alert System Status: El Niño Watch

ENSO-neutral conditions continue.*

Positive equatorial sea surface temperature (SST) anomalies continue across the Pacific Ocean.

There is a 58% chance of El Niño during the Northern Hemisphere winter, which is favored to last into the Northern Hemisphere spring 2015.*

* Note: These statements are updated once a month in association with the ENSO Diagnostics Discussion, which can be found by clicking here.
