## Internalization

Often a useful first step in the categorification process involves using a technique developed by Ehresmann called 'internalization.'

How do we do this?

- Given some concept, express its definition completely in terms of commutative diagrams.
- Now interpret these diagrams in some ambient category K.

We will consider the notion of a 'category in K' for various categories K.

A **strict 2-group** is a category in Grp, the category of groups.

A **2-vector space** is a category in Vect, the category of vector spaces.

A **2-vector space**, V, consists of:

- a vector space of objects, Ob(V)
- a vector space of morphisms, Mor(V)

together with:

• **linear** source and target maps

$$s, t \colon Mor(V) \to Ob(V),$$

 $\bullet$  a  $\mathbf{linear}$  identity-assigning map

$$i\colon Ob(V)\to Mor(V),$$

• a **linear** composition map

$$\circ \colon Mor(V) \times_{Ob(V)} Mor(V) \to Mor(V)$$

such that the following diagrams commute, expressing the usual category laws:

• laws specifying the source and target of identity morphisms:

$$\begin{array}{cccc} Ob(V) \xrightarrow{i} Mor(V) & Ob(V) \xrightarrow{i} Mor(V) \\ & & \downarrow s & & \downarrow t \\ Ob(V) & Ob(V) & Ob(V) \end{array}$$

• laws specifying the source and target of composite morphisms:

• the associative law for composition of morphisms:

• the left and right unit laws for composition of morphisms:

## 2-Vector Spaces

We can also define **linear functors** between 2-vector spaces, and **linear natural transformations** between these, in the obvious way.

**Theorem.** The 2-category of 2-vector spaces, linear functors and linear natural transformations is equivalent to the 2-category of:

- 2-term chain complexes  $C_1 \xrightarrow{d} C_0$ ,
- chain maps between these,
- chain homotopies between these.

#### Categorified Lie Theory, strictly speaking...

A strict Lie 2-group G is a category in LieGrp, the category of Lie groups.

A strict Lie 2-algebra L is a category in LieAlg, the category of Lie algebras.

We can also define **strict homomorphisms** between each of these and **strict 2-homomorphisms** between them, in the obvious way. Thus, we have two strict 2categories: SLie2Grp and SLie2Alg.

The picture here is very pretty: Just as Lie groups have Lie algebras, strict Lie 2-groups have strict Lie 2-algebras.

**Proposition.** There exists a unique 2-functor

 $d: SLie2Grp \rightarrow SLie2Alg$ 

#### **Examples of Strict Lie 2-Groups**

Let G be a Lie group and  $\mathfrak{g}$  its Lie algebra.

#### • Automorphism 2-Group

Objects : =  $\operatorname{Aut}(G)$ Morphisms : =  $G \rtimes \operatorname{Aut}(G)$ 

• Shifted U(1)

Objects : = \*Morphisms : = U(1)

• Tangent 2-Group

Objects : = GMorphisms :  $= \mathfrak{g} \rtimes G \cong TG$ 

• Poincaré 2-Group

# Semistrict Lie 2-Algebras

A semistrict Lie 2-algebra consists of:

 $\bullet$  a 2-vector space L

equipped with:

• a functor called the **bracket**:

 $[\cdot, \cdot] \colon L \times L \to L$ 

bilinear and skew-symmetric as a function of objects and morphisms,

• a natural isomorphism called the **Jacobiator**:

 $J_{x,y,z}: [[x,y],z] \to [x,[y,z]] + [[x,z],y],$ 

trilinear and antisymmetric as a function of the objects

x, y, z,

such that:

• the **Jacobiator identity** holds, meaning the following diagram commutes:

We can define **homomorphisms** between Lie 2-algebras, and **2-homomorphisms** between these.

Given Lie 2-algebras L and L', a **homomorphism**  $F: L \to L'$  consists of:

- a functor F from the underlying 2-vector space of L to that of L', linear on objects and morphisms,
- a natural isomorphism

$$F_2(x,y) \colon [F(x),F(y)] \to F[x,y],$$

bilinear and skew-symmetric as a function of the objects  $x, y \in L$ ,

such that:

• the following diagram commutes for all objects  $x, y, z \in L$ :

$$\begin{array}{c|c} [F(x), [F(y), F(z)]] & \xrightarrow{J_{F(x), F(y), F(z)}} & [[F(x), F(y)], F(z)] + [F(y), [F(x), F(z)]] \\ & & & & & \\ [1,F_2] & & & & & \\ [1,F_2] & & & & & \\ [F(x), F[y, z]] & & & & & \\ [F(x), F[y, z]] & & & & & \\ F_2 & & \\ F_2 & & \\ F_2 & & & \\ F_2 & & \\ F_2 & & & \\ F_2 & & & \\ F_2 & & \\ F_2 & & \\ F_2 & & \\ F_2 &$$

**Theorem.** The 2-category of Lie 2-algebras, homomorphisms and 2-homomorphisms is equivalent to the 2-category of:

- 2-term  $L_{\infty}$ -algebras,
- $L_{\infty}$ -homomorphisms between these,
- $L_{\infty}$ -2-homomorphisms between these.

The Lie 2-algebras L and L' are **equivalent** if there are homomorphisms

 $f \colon L \to L' \qquad \overline{f} \colon L' \to L$ 

that are inverses up to 2-isomorphism:

$$f\bar{f} \cong 1, \qquad \bar{f}f \cong 1.$$

**Theorem.** Lie 2-algebras are classified up to equivalence by quadruples consisting of:

- $\bullet$ a Lie algebra  ${\mathfrak g},$
- an abelian Lie algebra (= vector space)  $\mathfrak{h}$ ,
- a representation  $\rho$  of  $\mathfrak{g}$  on  $\mathfrak{h}$ ,
- an element  $[j] \in H^3(\mathfrak{g}, \mathfrak{h})$ .

## The Lie 2-Algebra $\mathfrak{g}_k$

Suppose  $\mathfrak{g}$  is a finite-dimensional simple Lie algebra over  $\mathbb{R}$ . To get a Lie 2-algebra having  $\mathfrak{g}$  as objects we need:

• a vector space  $\mathfrak{h}$ ,

• a representation 
$$\rho$$
 of  $\mathfrak{g}$  on  $\mathfrak{h}$ ,

• an element  $[j] \in H^3(\mathfrak{g}, \mathfrak{h})$ .

Assume without loss of generality that  $\rho$  is irreducible. To get Lie 2-algebras with nontrivial Jacobiator, we need  $H^3(\mathfrak{g},\mathfrak{h})\neq 0$ . By Whitehead's lemma, this only happens when  $\mathfrak{h} = \mathbb{R}$  is the trivial representation. Then we have

$$H^3(\mathfrak{g},\mathbb{R})=\mathbb{R}$$

with a nontrivial 3-cocycle given by:

$$\nu(x,y,z)=\langle [x,y],z\rangle.$$

The Lie algebra  $\mathfrak{g}$  together with the trivial representation of  $\mathfrak{g}$  on  $\mathbb{R}$  and k times the above 3-cocycle give the Lie 2-algebra  $\mathfrak{g}_k$ .

In summary: every simple Lie algebra  $\mathfrak{g}$  gives a oneparameter family of Lie 2-algebras,  $\mathfrak{g}_k$ , which reduces to  $\mathfrak{g}$  when k = 0!

**Puzzle:** Does  $\mathfrak{g}_k$  come from a Lie 2-group?

## Coherent 2-Groups

A **coherent 2-group** is a weak monoidal category in which every morphism is invertible and every object is equipped with an adjoint equivalence.

A **homomorphism** between coherent 2-groups is a weak monoidal functor. A **2-homomorphism** is a monoidal natural transformation. The coherent 2-groups X and X' are **equivalent** if there are homomorphisms

$$f: X \to X' \qquad \overline{f}: X' \to X$$

that are inverses up to 2-isomorphism:

$$f\bar{f} \cong 1, \qquad \bar{f}f \cong 1.$$

**Theorem.** Coherent 2-groups are classified up to equivalence by quadruples consisting of:

- a group G,
- $\bullet$  an abelian group H,
- an action  $\alpha$  of G as automorphisms of H,
- an element  $[a] \in H^3(G, H)$ .

Suppose we try to copy the construction of  $\mathfrak{g}_k$  for a particularly nice kind of Lie group. Let G be a simplyconnected compact simple Lie group whose Lie algebra is  $\mathfrak{g}$ . We have

$$H^3(G, \mathrm{U}(1)) \xrightarrow{\iota} \mathbb{Z} \hookrightarrow \mathbb{R} \cong H^3(\mathfrak{g}, \mathbb{R})$$

Using the classification of 2-groups, we can build a skeletal 2-group  $G_k$  for  $k \in \mathbb{Z}$ :

- G as its group of objects,
- U(1) as the group of automorphisms of any object,
- the trivial action of G on U(1),
- $[a] \in H^3(G, U(1))$  given by  $k \iota[\nu]$ , which is nontrivial when  $k \neq 0$ .

**Question:** Can  $G_k$  be made into a Lie 2-group?

Here's the bad news:

(Bad News) Theorem. Unless k = 0, there is no way to give the 2-group  $G_k$  the structure of a Lie 2-group for which the group G of objects and the group U(1) of endomorphisms of any object are given their usual topology.

(Good News) Theorem. For any  $k \in \mathbb{Z}$ , there is a Fréchet Lie 2-group  $\mathcal{P}_k G$  whose Lie 2-algebra  $\mathcal{P}_k \mathfrak{g}$  is equivalent to  $\mathfrak{g}_k$ .

An object of  $\mathcal{P}_k G$  is a smooth path  $f: [0, 2\pi] \to G$  starting at the identity. A morphism from  $f_1$  to  $f_2$  is an equivalence class of pairs  $(D, \alpha)$  consisting of a disk D going from  $f_1$  to  $f_2$  together with  $\alpha \in \mathrm{U}(1)$ :

For any two such pairs  $(D_1, \alpha_1)$  and  $(D_2, \alpha_2)$  there is a 3-ball *B* whose boundary is  $D_1 \cup D_2$ , and the pairs are equivalent when

$$\exp\left(2\pi ik\int_B\nu\right) = \alpha_2/\alpha_1$$

where  $\nu$  is the left-invariant closed 3-form on G with

$$\nu(x,y,z) = \langle [x,y],z\rangle$$

and  $\langle \cdot, \cdot \rangle$  is the smallest invariant inner product on  $\mathfrak{g}$  such that  $\nu$  gives an integral cohomology class.

## $\mathcal{P}_k G$ and Loop Groups

We can also describe the 2-group  $\mathcal{P}_k G$  as follows:

- An object of  $\mathcal{P}_k G$  is a smooth path in G starting at the identity.
- Given objects  $f_1, f_2 \in \mathcal{P}_k G$ , a morphism

$$\widehat{\ell} \colon f_1 \to f_2$$

is an element  $\widehat{\ell} \in \widehat{\Omega_k G}$  with

$$p(\widehat{\ell}) = f_2 / f_1$$

where  $\widehat{\Omega}_k \widehat{G}$  is the level-k Kac–Moody central extension of the loop group  $\Omega G$ :

$$1 \longrightarrow \mathrm{U}(1) \longrightarrow \widehat{\Omega_k G} \stackrel{p}{\longrightarrow} \Omega G \longrightarrow 1$$

Remark:  $p(\hat{\ell})$  is a loop in G. We can get such a loop with

$$p(\widehat{\ell}) = f_2/f_1$$

from a disk D like this:

### The Lie 2-Group $\mathcal{P}_k G$

Thus,  $\mathcal{P}_k G$  is described by the following where  $p \in P_0 G$ and  $\hat{\gamma} \in \widehat{\Omega_k G}$ :

• A Fréchet Lie group of **objects**:

 $\operatorname{Ob}(\mathcal{P}_k G) = P_0 G$ 

• A Fréchet Lie group of **morphisms**:

$$Mor(\mathcal{P}_k G) = P_0 G \ltimes \widehat{\Omega_k G}$$

- source map:  $s(p, \hat{\gamma}) = p$
- target map:  $t(p, \hat{\gamma}) = p\partial(\hat{\gamma})$  where  $\partial$  is defined as the composite

$$\widehat{\Omega_k G} \xrightarrow{p} \Omega G \xrightarrow{i} P_0 G$$

- composition:  $(p_1, \hat{\gamma}_1) \circ (p_2, \hat{\gamma}_2) = (p_1, \hat{\gamma}_1 \hat{\gamma}_2)$  when  $t(p_1, \hat{\gamma}_1) = s(p_2, \hat{\gamma}_2)$ , or  $p_2 = p_1 \partial(\hat{\gamma}_1)$
- identities: i(p) = (p, 1)

## Topology of $\mathcal{P}_k G$

The **nerve** of any topological 2-group is a **simplicial** topological group and therefore when we take the **geo-metric realization** we obtain a topological group:

**Theorem.** For any  $k \in \mathbb{Z}$ , the geometric realization of the nerve of  $\mathcal{P}_k G$  is a topological group  $|\mathcal{P}_k G|$ . We have

$$\pi_3(|\mathcal{P}_kG|) \cong \mathbb{Z}/k\mathbb{Z}$$

When  $k = \pm 1$ ,

$$|\mathcal{P}_k G| \simeq \widehat{G},$$

which is the topological group obtained by killing the third homotopy group of G.

When G = Spin(n),  $\widehat{G}$  is called String(n). When  $k = \pm 1$ ,  $|\mathcal{P}_k G| \simeq \widehat{G}$ .

## The Lie 2-Algebra $\mathcal{P}_k \mathfrak{g}$

 $\mathcal{P}_k G$  is a particularly nice kind of Lie 2-group: a *strict* one! Thus, its Lie 2-algebra is easy to compute. Moreover,

Theorem.  $\mathcal{P}_k \mathfrak{g} \simeq \mathfrak{g}_k$ 

# Questions

We know how to get Lie n-algebras from Lie algebra cohomology! We should:

- Classify their representations
- Find their corresponding Lie n-groups
- Understand their relation to higher braid theory
