

Footnote to <http://math.ucr.edu/~res/math133/examples0101.pdf>:

Strictly speaking, one needs to prove that the vector  $\mathbf{c}$  lies in the interior of  $\angle \mathbf{a}\mathbf{0}\mathbf{b}$ , but one obstacle to doing so is that the interior of an angle is not defined in Unit **I**. However, this follows directly from Proposition **II.3.3** (see page **61** of the notes) because  $\mathbf{c}$  is a linear combination of  $\mathbf{a}$  and  $\mathbf{b}$  in which both coefficients are positive by construction (of course, we can also retrieve the barycentric coordinate of  $\mathbf{0}$  because the sum of the barycentric coordinates is always equal to **1**).
