## Supplement to Chapter 11 of Sutherland, <br> Introduction to Metric and Topological Spaces (Second Edition)

The Hausdorff Separation Property for Metric Spaces is apparent from the following drawing, in which $\mathbf{U}$ and $\mathbf{V}$ are open disks with centers $\mathbf{x}$ and $\mathbf{y}$. The respective radii are $\mathbf{a}$ and $\mathbf{b}$, where the latter are assumed to satisfy $\mathbf{a}+\mathbf{b}<\mathbf{d}(\mathbf{x}, \mathbf{y})$. This is slightly more general than the situation described in Sutherland.

For the sake of completeness, here is a proof that $\mathbf{U}$ and $\mathbf{V}$ are disjoint. If $\mathbf{z}$ is a point belonging to both open subsets then by hypothesis $\mathbf{d}(\mathbf{z}, \mathbf{x})<\mathbf{a}$ and $\mathbf{d}(\mathbf{z}, \mathbf{y})<\mathbf{b}$. Then the Triangle Inequality implies that

$$
d(x, y) \leq d(x, z)+d(z, y)<a+b<d(x, y)
$$

which is a contradiction. The source of this contradiction is the assumption that $\mathbf{U}$ and $\mathbf{V}$ have a common point, so no such point can exist.
