

3.B. Geometric proportions and the Condition of Eudoxus

One important motivation for the Condition of Eudoxus was to consider geometric ratios involving *incommensurable quantities*; in modern language, these are lengths $|WX|$ and $|YZ|$ such that the quotient $|WX|/|YZ|$ is not a rational number. A basic problem of this nature is depicted in the figure below:

In this picture the lines BD and CE are assumed to be parallel, and one wants to prove that

$$|AB|/|AC| = |AD|/|AE|.$$

If the left hand side is a rational number p/q , then standard manipulations of ratios show that

$$|AB|/p = |AC|/q$$

and ideas discussed in the proof of the *Notebook Paper Theorem* imply that

$$|AD|/p = |AE|/q$$

which then quickly yields $|AD|/|AE| = p/q = |AB|/|AC|$. Of course, this argument breaks down completely for ratios $|AB|/|AC|$ which are equal to irrational numbers like $\sqrt{2}$, and we need the Condition of Eudoxus to handle such cases.

Here is a formal statement of Eudoxus' criterion for two ratios to be equal:

Two ratios of (positive real) numbers a/b and c/d are equal if and only if for each pair of positive integers m and n we have the following:

$$ma < nb \quad \text{implies} \quad mc < nd$$

$$ma > nb \quad \text{implies} \quad mc > nd$$

The derivation of this criterion is based upon a fundamentally important **rational density property** of the real numbers:

If we are given real numbers x and y such that $x < y$, then there is a rational number r such that $x < r < y$.

Further details about this implication are contained in the first supplement to this unit (see <http://www.math.ucr.edu/~res/math153/history03a.pdf>).

APPLICATION OF THE CONDITION OF EUDOXUS TO PROPORTIONALITY

QUESTIONS. Suppose now that we have triangles $\triangle ABD$ and $\triangle ACE$ as in the figure below, where BD is parallel to CE ; as in the figure we assume that the rays $[AB$ and $[AC$ are the same and likewise that the rays $[AD$ and $[AE$ are the same. Let $a = |AB|$, $b = |AC|$, $c = |AD|$ and $d = |AE|$. We want to use the Condition of Eudoxus to conclude that $a/b = c/d$.

Suppose first that m and n are positive integers such that $ma < nb$. We want to show that $mc < nd$. We can find points P and Q on the ray $[AB = [AC$ such that $|AP| = ma$ and $|AQ| = nb$. Since $ma < nb$, it follows that P is between A and Q . One can then find unique parallel lines to BD and CE through P and Q . These two lines will meet the line $AD = AE$ in two points R and S . A proper formulation of concepts like betweenness, the two sides of a line, and so on will imply that S and R also lie on the ray $[AD = [AE$ and that R is between A and S .

The proportionality results in the commensurable case now imply that

$$|AR|/|AD| = m = |AP|/|AB| \quad \text{and}$$

$$|AS|/|AE| = n = |AQ|/|AC|.$$

Therefore $|AR| = mc$ and $|AS| = nd$ also hold. By observations in the previous paragraph we know that $|AR| < |AS|$, and thus we may use the preceding sentences to rewrite this as $mc < nd$. To summarize, we have now shown that $ma < nb$ implies $mc < nd$.

If we have $ma > nb$, then we may proceed similarly. The argument is basically the same except that **Q** will be between **A** and **P**, and this will in turn imply that **S** is between **A** and **R**. Following the same line of reasoning in this case, one concludes that $ma > nb$ implies $mc > nd$. Therefore we have established both parts of the Condition of Eudoxus, and consequently we have shown that $a/b = c/d$; by definition of the numbers a, b, c, d in this equation, the desired proportionality equation $|AB|/|AC| = |AD|/|AE|$ is an immediate consequence.
