FIGURES FOR ALGEBRAIC TOPOLOGY LECTURE NOTES

I: Foundatonal and geometric background

I.2: Barycentric coordinates and polyhedra

Barycentric coordinates. In the drawing below, each of the points P, Q, R lies in the plane determined by P₁, P₂, and P₃, and consequently each can be written as a linear combination $w_1P_1 + w_2P_2 + w_3P_3$, where $w_1 + w_2 + w_3 = 1$. For the point P, the barycentric coordinates w_i are all positive, while for the point R the barycentric coordinates are such that $w_1 = 0$ but the other two are positive, and for the point Q the barycentric coordinates are such that w_1 is negative but the other two are positive.

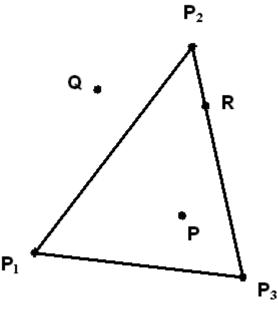

FIGURE 1

(Source: http://graphics.idav.ucdavis.edu/education/GraphicsNotes/Barycentric-Coordinates/Barycentric-Coordinates.html)

Examples of points for which w_2 is positive but the remaining coordinates are negative can also be constructed using this picture; for example, if one takes the midpoint **M** of the segment $[P_1P_3]$, then the point $S = 2P_2 - M$ will have this property (geometrically, P_2 is the midpoint of the segment joining **M** and **S**).

<u>Illustration of a 2 - simplex</u>. We shall use a modified version of Figure 1; the points of the 2 - simplex with vertices P_1 , P_2 , and P_3 consists of the triangle determined by these points and the points which lie inside this triangle (in the usual intuitive sense of the word).</u>

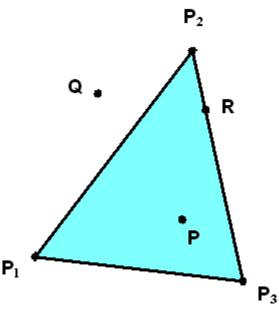

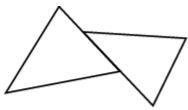

FIGURE 2

In this picture the points **P** and **R** lie on the simplex $P_1P_2P_3$ because their barycentric coordinates are all nonnegative, but the point **Q** does not because one of its barycentric coordinates is negative.

Note that the (*proper*) *faces* of this simplex are the closed segments P_1P_2 , P_2P_3 , and P_1P_3 joining pairs of vertices as well as the three vertices themselves (and possibly the empty set if we want to talk about an empty face with no vertices).

<u>Simplicial decompositions.</u> It is useful to look at a few spaces given as unions of 2 - simplices, some of which determine simplicial complexes in the sense of the notes and others that do not.

not a simplicial complex FIGURE 3

(Source: http://mathworld.wolfram.com/SimplicialComplex.html)

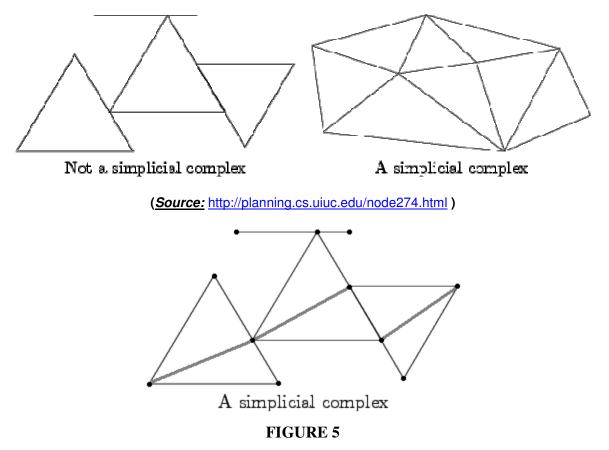

In the example above the intersection of the 2- simplices is not a common face. On the other hand, we can split the two simplices into smaller pieces such that we do have a simplicial decomposition.

simplicial complex

FIGURE 4

Here are two more examples; in the second case the simplices determine a simplicial complex and in the first they do not. As in the preceding example, one can subdivide the simplices in the first example to obtain a simplicial decomposition.

<u>Triangulations.</u> In the example from page 523 of Marsden and Tromba, the annulus bounded by two circles is split into four isometric pieces as in the drawing on the next page.

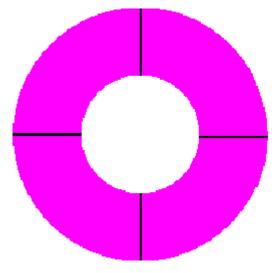

FIGURE 6

Each of the four pieces is homeomorphic to a solid rectangle. Since a solid rectangle has a simplicial decomposition into two 2 – simplices, one can use such a decomposition to form a triangulation of the solid annulus.

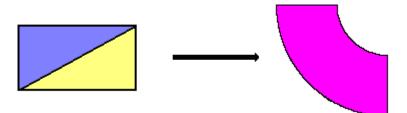

FIGURE 7

A closely related way of triangulating the annulus is suggested by the figure below:

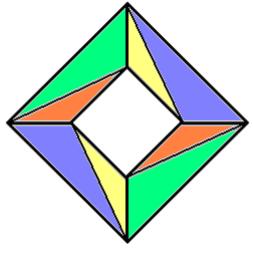

FIGURE 8

Similarly, many familiar closed polygonal regions can be triangulated fairly easily. Here is an example for a solid hexagon.

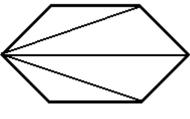

FIGURE 9

<u>**Triangulations of prisms.</u>** The drawings below illustrate the standard decomposition of a 3 - dimensional triangular prism.</u>

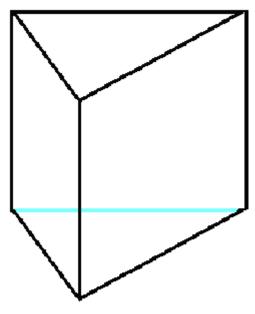

FIGURE 10

If we take x_0 , x_1 , and x_2 to be the vertices of the bottom triangle and y_0 , y_1 , and y_2 to be the vertices of the top triangle, then the decomposition is given as follows:

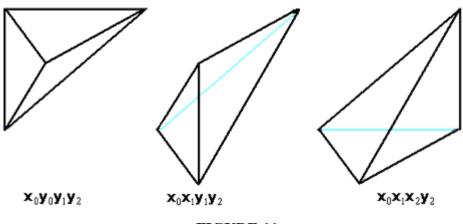

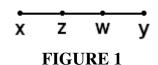

FIGURE 11

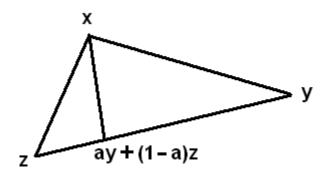

I.3: Subdivisions

<u>Simple subdivisions 1.</u> The drawing below depicts a subdivision of a 1 -simplex given by a closed interval in the real line into three 1 -simplices (which are just subintervals of the original interval).

Similarly, every partition of an interval determines a subdivision.

<u>Simple subdivisions 2.</u> The drawing below depicts a subdivision of a 2 - simplex into two 2 - simplices.

If $\mathbf{w} = a\mathbf{y} + (1-a)\mathbf{z}$ where 0 < a < 1 and $p\mathbf{x} + q\mathbf{y} + r\mathbf{z}$ is a point on the simplex **xyz** (so that $p, q, r \ge 0$ and $p\mathbf{x} + q\mathbf{y} + r\mathbf{z} = 1$), then the point $p\mathbf{x} + q\mathbf{y} + r\mathbf{z}$ lies on the simplex **xwz** if and only if p = 1 or p < 1 and $q \ge a(1-p)$, and $p\mathbf{x} + q\mathbf{y} + r\mathbf{z}$ lies on the simplex **xwy** if and only if p = 1 or p < 1 and $q \le a(1-p)$. The intersection of these simplices is the face with vertices **x** and **w**. Some other simple subdivisions of a 2 - simplex are illustrated below.

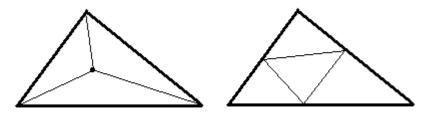

FIGURE 3

<u>A nonexample.</u> In general, if we given two simplicial decompositions, then neither is a subdivision of the other. For example, neither of the two simplicial decompositions of a rectangle described below is a subdivision of the other.

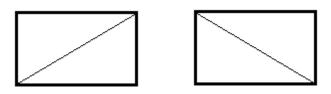

FIGURE 4

On the other hand, there is a decomposition which is a subdivision of **both** the decompositions shown above.

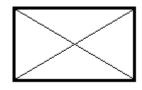

FIGURE 5

More generally, if we are given two simplicial decompositions K and L of a polyhedron P then one can always construct a third decomposition which is a subdivision of both K and L. This follows from results in the book, *Elementary Differential Topology*, by J. R. Munkres (see the notes for a more complete citation).

<u>**Barycentric subdivisions.**</u> Here is a drawing to illustrate the barycentric subdivision of a 2 -simplex.

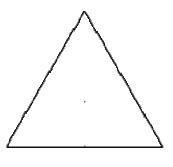

FIGURE 6

The vertices of a 2 – simplex in this subdivision are given by **a**, **b** and **c**, where **a** is a vertex of the original simplex, **b** is the midpoint of an edge which has **a** as a vertex, and **c** is the barycenter of the 2 – simplex itself. In this example, the diameters of the 2 – simplices in the barycentric subdivision are 2/3 the diameter of the original simplex.

The drawing below illustrates the barycentric subdivision of a solid rectangular region with its basic decomposition into two 2 - simplices along a diagonal.

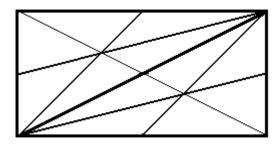

FIGURE 7

The next drawing illustrates the *second barycentric subdivision* of a 2 - simplex (however, the locations of several vertices are slightly inaccurate).

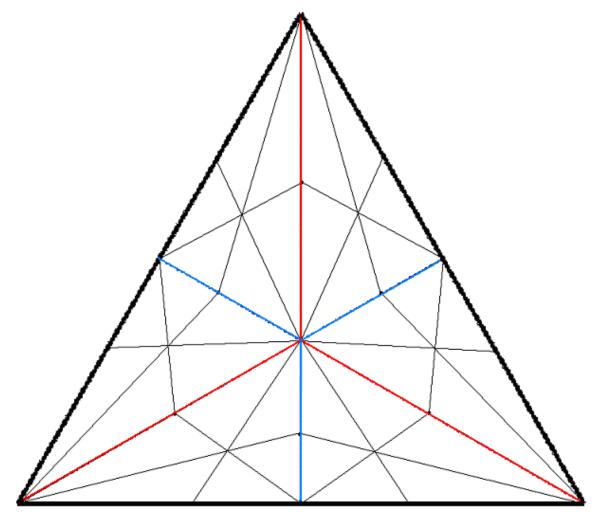

FIGURE 8

This decomposition has 25 vertices, 60 edges and 36 simplices that are 2 - dimensional. Incidentally, in the third barycentric subdivision there are 121 vertices, 336 edges and 216 simplices that are 2 - dimensional.

I.4 : Cones and suspensions

<u>**Cones.**</u> In the simplest cases, Proposition 1 implies that the topological cones on spaces are canonically homeomorphic to the standard cones of elementary geometry. For example, if X is the circle S^1 , then Proposition 1 shows that the cone on X is homeomorphic to the lateral (or top) surface of the cone illustrated below, and if X is the disk D^2 , then Proposition 1 shows that the cone on X is homeomorphic to the solid cone.

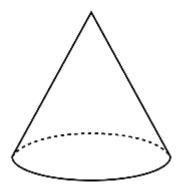

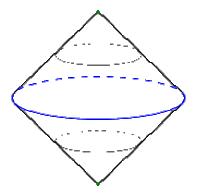

FIGURE 9

Suspensions. The drawing below illustrates the suspension of the circle. Note that the closure of the piece above the xy – plane is merely the cone on the circle, while the closure of the piece below the xy – plane is the mirror image of that cone with respect to reflection about the xy – plane.

(See the Wikipedia citation in http://www.answers.com/topic/suspension)

FIGURE 10

In this drawing, the original space is in blue, and the collapsed end points (the "poles") are both in green.
