

5: INTEGRATION

We have spent considerable time considering the derivatives of a function and their applications. In the following chapters, we are going to start thinking in “the other direction.” That is, given a function $f(x)$, we are going to consider functions $F(x)$ such that $F'(x) = f(x)$. There are numerous reasons this will prove to be useful: these functions will help us compute area, volume, mass, force, pressure, work, and much more.

5.1 Antiderivatives and Indefinite Integration

Given a function $y = f(x)$, a *differential equation* is one that incorporates y , x , and the derivatives of y . For instance, a simple differential equation is:

$$y' = 2x.$$

Solving a differential equation amounts to finding a function y that satisfies the given equation. Take a moment and consider that equation; can you find a function y such that $y' = 2x$?

Can you find another?

And yet another?

Hopefully one was able to come up with at least one solution: $y = x^2$. “Finding another” may have seemed impossible until one realizes that a function like $y = x^2 + 1$ also has a derivative of $2x$. Once that discovery is made, finding “yet another” is not difficult; the function $y = x^2 + 123,456,789$ also has a derivative of $2x$. The differential equation $y' = 2x$ has many solutions. This leads us to some definitions.

Definition 5.1.1 Antiderivatives and Indefinite Integrals

Let a function $f(x)$ be given. An **antiderivative** of $f(x)$ is a function $F(x)$ such that $F'(x) = f(x)$.

The set of all antiderivatives of $f(x)$ is the **indefinite integral of f** , denoted by

$$\int f(x) dx.$$

Make a note about our definition: we refer to *an* antiderivative of f , as opposed to *the* antiderivative of f , since there is *always* an infinite number of them.

We often use upper-case letters to denote antiderivatives.

Knowing one antiderivative of f allows us to find infinitely more, simply by adding a constant. Not only does this give us *more* antiderivatives, it gives us *all* of them.

Theorem 5.1.1 Antiderivative Forms

Let $F(x)$ and $G(x)$ be antiderivatives of $f(x)$ on an interval I . Then there exists a constant C such that, on I ,

$$G(x) = F(x) + C.$$

Given a function f defined on an interval I and one of its antiderivatives F , we know *all* antiderivatives of f on I have the form $F(x) + C$ for some constant C . Using Definition 5.1.1, we can say that

$$\int f(x) dx = F(x) + C.$$

Let's analyze this indefinite integral notation.

Figure 5.1.1: Understanding the indefinite integral notation.

Figure 5.1.1 shows the typical notation of the indefinite integral. The integration symbol, \int , is in reality an "elongated S," representing "take the sum." We will later see how *sums* and *antiderivatives* are related.

The function we want to find an antiderivative of is called the *integrand*. It contains the differential of the variable we are integrating with respect to. The \int symbol and the differential dx are not "bookends" with a function sandwiched in between; rather, the symbol \int means "find all antiderivatives of what follows," and the function $f(x)$ and dx are multiplied together; the dx does not "just sit there."

Let's practice using this notation.

Notes:

Example 5.1.1 Evaluating indefinite integrals

Evaluate $\int \sin x \, dx$.

SOLUTION We are asked to find all functions $F(x)$ such that $F'(x) = \sin x$. Some thought will lead us to one solution: $F(x) = -\cos x$, because $\frac{d}{dx}(-\cos x) = \sin x$.

The indefinite integral of $\sin x$ is thus $-\cos x$, plus a constant of integration.

So:

$$\int \sin x \, dx = -\cos x + C.$$

A commonly asked question is “What happened to the dx ?” The unenlightened response is “Don’t worry about it. It just goes away.” A full understanding includes the following.

This process of *antidifferentiation* is really solving a *differential* question. The integral

$$\int \sin x \, dx$$

presents us with a differential, $dy = \sin x \, dx$. It is asking: “What is y ?” We found lots of solutions, all of the form $y = -\cos x + C$.

Letting $dy = \sin x \, dx$, rewrite

$$\int \sin x \, dx \quad \text{as} \quad \int dy.$$

This is asking: “What functions have a differential of the form dy ?” The answer is “Functions of the form $y + C$, where C is a constant.” What is y ? We have lots of choices, all differing by a constant; the simplest choice is $y = -\cos x$.

Understanding all of this is more important later as we try to find antiderivatives of more complicated functions. In this section, we will simply explore the rules of indefinite integration, and one can succeed for now with answering “What happened to the dx ?” with “It went away.”

Let’s practice once more before stating integration rules.

Example 5.1.2 Evaluating indefinite integrals

Evaluate $\int (3x^2 + 4x + 5) \, dx$.

SOLUTION We seek a function $F(x)$ whose derivative is $3x^2 + 4x + 5$. When taking derivatives, we can consider functions term-by-term, so we can likely do that here.

What functions have a derivative of $3x^2$? Some thought will lead us to a cubic, specifically $x^3 + C_1$, where C_1 is a constant.

Notes:

What functions have a derivative of $4x$? Here the x term is raised to the first power, so we likely seek a quadratic. Some thought should lead us to $2x^2 + C_2$, where C_2 is a constant.

Finally, what functions have a derivative of 5? Functions of the form $5x + C_3$, where C_3 is a constant.

Our answer appears to be

$$\int (3x^2 + 4x + 5) dx = x^3 + C_1 + 2x^2 + C_2 + 5x + C_3.$$

We do not need three separate constants of integration; combine them as one constant, giving the final answer of

$$\int (3x^2 + 4x + 5) dx = x^3 + 2x^2 + 5x + C.$$

It is easy to verify our answer; take the derivative of $x^3 + 2x^2 + 5x + C$ and see we indeed get $3x^2 + 4x + 5$.

This final step of “verifying our answer” is important both practically and theoretically. In general, taking derivatives is easier than finding antiderivatives so checking our work is easy and vital as we learn.

We also see that taking the derivative of our answer returns the function in the integrand. Thus we can say that:

$$\frac{d}{dx} \left(\int f(x) dx \right) = f(x).$$

Differentiation “undoes” the work done by antidifferentiation.

Theorem 2.7.3 gave a list of the derivatives of common functions we had learned at that point. We restate part of that list here to stress the relationship between derivatives and antiderivatives. This list will also be useful as a glossary of common antiderivatives as we learn.

Notes:

Theorem 5.1.2 Derivatives and Antiderivatives

Common Differentiation Rules Common Indefinite Integral Rules

1. $\frac{d}{dx}(cf(x)) = c \cdot f'(x)$	1. $\int c \cdot f(x) dx = c \cdot \int f(x) dx$
2. $\frac{d}{dx}(f(x) \pm g(x)) = f'(x) \pm g'(x)$	2. $\int (f(x) \pm g(x)) dx = \int f(x) dx \pm \int g(x) dx$
3. $\frac{d}{dx}(C) = 0$	3. $\int 0 dx = C$
4. $\frac{d}{dx}(x) = 1$	4. $\int 1 dx = \int dx = x + C$
5. $\frac{d}{dx}(x^n) = n \cdot x^{n-1}$	5. $\int x^n dx = \frac{1}{n+1}x^{n+1} + C \quad (n \neq -1)$
6. $\frac{d}{dx}(\sin x) = \cos x$	6. $\int \cos x dx = \sin x + C$
7. $\frac{d}{dx}(\cos x) = -\sin x$	7. $\int \sin x dx = -\cos x + C$
8. $\frac{d}{dx}(\tan x) = \sec^2 x$	8. $\int \sec^2 x dx = \tan x + C$
9. $\frac{d}{dx}(\csc x) = -\csc x \cot x$	9. $\int \csc x \cot x dx = -\csc x + C$
10. $\frac{d}{dx}(\sec x) = \sec x \tan x$	10. $\int \sec x \tan x dx = \sec x + C$
11. $\frac{d}{dx}(\cot x) = -\csc^2 x$	11. $\int \csc^2 x dx = -\cot x + C$
12. $\frac{d}{dx}(e^x) = e^x$	12. $\int e^x dx = e^x + C$
13. $\frac{d}{dx}(a^x) = \ln a \cdot a^x$	13. $\int a^x dx = \frac{1}{\ln a} \cdot a^x + C$
14. $\frac{d}{dx}(\ln x) = \frac{1}{x}$	14. $\int \frac{1}{x} dx = \ln x + C$

We highlight a few important points from Theorem 5.1.2:

- Rule #1 states $\int c \cdot f(x) dx = c \cdot \int f(x) dx$. This is the Constant Multiple Rule: we can temporarily ignore constants when finding antiderivatives, just as we did when computing derivatives (i.e., $\frac{d}{dx}(3x^2)$ is just as easy to compute as $\frac{d}{dx}(x^2)$). An example:

$$\int 5 \cos x dx = 5 \cdot \int \cos x dx = 5 \cdot (\sin x + C) = 5 \sin x + C.$$

In the last step we can consider the constant as also being multiplied by

Notes:

5, but “5 times a constant” is still a constant, so we just write “ C ”.

- Rule #2 is the Sum/Difference Rule: we can split integrals apart when the integrand contains terms that are added/subtracted, as we did in Example 5.1.2. So:

$$\begin{aligned}\int (3x^2 + 4x + 5) dx &= \int 3x^2 dx + \int 4x dx + \int 5 dx \\ &= 3 \int x^2 dx + 4 \int x dx + \int 5 dx \\ &= 3 \cdot \frac{1}{3}x^3 + 4 \cdot \frac{1}{2}x^2 + 5x + C \\ &= x^3 + 2x^2 + 5x + C\end{aligned}$$

In practice we generally do not write out all these steps, but we demonstrate them here for completeness.

- Rule #5 is the Power Rule of indefinite integration. There are two important things to keep in mind:
 1. Notice the restriction that $n \neq -1$. This is important: $\int \frac{1}{x} dx \neq \frac{1}{0}x^0 + C$; rather, see Rule #14.
 2. We are presenting antidifferentiation as the “inverse operation” of differentiation. Here is a useful quote to remember:

“Inverse operations do the opposite things in the opposite order.”

When taking a derivative using the Power Rule, we **first multiply** by the power, then **second subtract** 1 from the power. To find the antiderivative, do the opposite things in the opposite order: **first add** one to the power, then **second divide** by the power.
- Note that Rule #14 incorporates the absolute value of x . The exercises will work the reader through why this is the case; for now, know the absolute value is important and cannot be ignored.

Initial Value Problems

In Section 2.3 we saw that the derivative of a position function gave a velocity function, and the derivative of a velocity function describes acceleration. We can now go “the other way:” the antiderivative of an acceleration function gives a velocity function, etc. While there is just one derivative of a given function, there are infinitely many antiderivatives. Therefore we cannot ask “What is *the* velocity of an object whose acceleration is -32ft/s^2 ?”, since there is more than one answer.

Notes:

We can find *the* answer if we provide more information with the question, as done in the following example. Often the additional information comes in the form of an *initial value*, a value of the function that one knows beforehand.

Example 5.1.3 Solving initial value problems

The acceleration due to gravity of a falling object is -32 ft/s^2 . At time $t = 3$, a falling object had a velocity of -10 ft/s . Find the equation of the object's velocity.

SOLUTION We want to know a velocity function, $v(t)$. We know two things:

- The acceleration, i.e., $v'(t) = -32$, and
- the velocity at a specific time, i.e., $v(3) = -10$.

Using the first piece of information, we know that $v(t)$ is an antiderivative of $v'(t) = -32$. So we begin by finding the indefinite integral of -32 :

$$\int (-32) dt = -32t + C = v(t).$$

Now we use the fact that $v(3) = -10$ to find C :

$$\begin{aligned} v(t) &= -32t + C \\ v(3) &= -10 \\ -32(3) + C &= -10 \\ C &= 86 \end{aligned}$$

Thus $v(t) = -32t + 86$. We can use this equation to understand the motion of the object: when $t = 0$, the object had a velocity of $v(0) = 86 \text{ ft/s}$. Since the velocity is positive, the object was moving upward.

When did the object begin moving down? Immediately after $v(t) = 0$:

$$-32t + 86 = 0 \quad \Rightarrow \quad t = \frac{43}{16} \approx 2.69\text{s}.$$

Recognize that we are able to determine quite a bit about the path of the object knowing just its acceleration and its velocity at a single point in time.

Example 5.1.4 Solving initial value problems

Find $f(t)$, given that $f''(t) = \cos t$, $f'(0) = 3$ and $f(0) = 5$.

SOLUTION We start by finding $f'(t)$, which is an antiderivative of $f''(t)$:

$$\int f''(t) dt = \int \cos t dt = \sin t + C = f'(t).$$

Notes:

So $f'(t) = \sin t + C$ for the correct value of C . We are given that $f'(0) = 3$, so:

$$f'(0) = 3 \Rightarrow \sin 0 + C = 3 \Rightarrow C = 3.$$

Using the initial value, we have found $f'(t) = \sin t + 3$.

We now find $f(t)$ by integrating again.

$$f(t) = \int f'(t) dt = \int (\sin t + 3) dt = -\cos t + 3t + C.$$

We are given that $f(0) = 5$, so

$$-\cos 0 + 3(0) + C = 5$$

$$-1 + C = 5$$

$$C = 6$$

Thus $f(t) = -\cos t + 3t + 6$.

This section introduced antiderivatives and the indefinite integral. We found they are needed when finding a function given information about its derivative(s). For instance, we found a velocity function given an acceleration function.

In the next section, we will see how position and velocity are unexpectedly related by the areas of certain regions on a graph of the velocity function. Then, in Section 5.4, we will see how areas and antiderivatives are closely tied together. This connection is incredibly important, as indicated by the name of the theorem that describes it: The Fundamental Theorem of Calculus.

Notes:

Exercises 5.1

Terms and Concepts

1. Define the term “antiderivative” in your own words.
2. Is it more accurate to refer to “the” antiderivative of $f(x)$ or “an” antiderivative of $f(x)$?
3. Use your own words to define the indefinite integral of $f(x)$.
4. Fill in the blanks: “Inverse operations do the _____ things in the _____ order.”
5. What is an “initial value problem”?
6. The derivative of a position function is a _____ function.
7. The antiderivative of an acceleration function is a _____ function.
8. If $F(x)$ is an antiderivative of $f(x)$, and $G(x)$ is an antiderivative of $g(x)$, give an antiderivative of $f(x) + g(x)$.

Problems

In Exercises 9 – 27, evaluate the given indefinite integral.

9. $\int 3x^3 dx$
10. $\int x^8 dx$
11. $\int (10x^2 - 2) dx$
12. $\int dt$
13. $\int 1 ds$
14. $\int \frac{1}{3t^2} dt$
15. $\int \frac{3}{t^2} dt$
16. $\int \frac{1}{\sqrt{x}} dx$
17. $\int \sec^2 \theta d\theta$
18. $\int \sin \theta d\theta$

$$19. \int (\sec x \tan x + \csc x \cot x) dx$$

$$20. \int 5e^{\theta} d\theta$$

$$21. \int 3^t dt$$

$$22. \int \frac{5^t}{2} dt$$

$$23. \int (2t + 3)^2 dt$$

$$24. \int (t^2 + 3)(t^3 - 2t) dt$$

$$25. \int x^2 x^3 dx$$

$$26. \int e^{\pi} dx$$

$$27. \int a dx$$

28. This problem investigates why Theorem 5.1.2 states that

$$\int \frac{1}{x} dx = \ln |x| + C.$$

(a) What is the domain of $y = \ln x$?

(b) Find $\frac{d}{dx}(\ln x)$.

(c) What is the domain of $y = \ln(-x)$?

(d) Find $\frac{d}{dx}(\ln(-x))$.

(e) You should find that $1/x$ has two types of antiderivatives, depending on whether $x > 0$ or $x < 0$. In one expression, give a formula for $\int \frac{1}{x} dx$ that takes these different domains into account, and explain your answer.

In Exercises 29 – 39, find $f(x)$ described by the given initial value problem.

$$29. f'(x) = \sin x \text{ and } f(0) = 2$$

$$30. f'(x) = 5e^x \text{ and } f(0) = 10$$

$$31. f'(x) = 4x^3 - 3x^2 \text{ and } f(-1) = 9$$

$$32. f'(x) = \sec^2 x \text{ and } f(\pi/4) = 5$$

$$33. f'(x) = 7^x \text{ and } f(2) = 1$$

$$34. f''(x) = 5 \text{ and } f'(0) = 7, f(0) = 3$$

$$35. f''(x) = 7x \text{ and } f'(1) = -1, f(1) = 10$$

36. $f''(x) = 5e^x$ and $f'(0) = 3, f(0) = 5$

37. $f''(\theta) = \sin \theta$ and $f'(\pi) = 2, f(\pi) = 4$

38. $f''(x) = 24x^2 + 2^x - \cos x$ and $f'(0) = 5, f(0) = 0$

39. $f''(x) = 0$ and $f'(1) = 3, f(1) = 1$

Review

40. Use information gained from the first and second derivatives to sketch $f(x) = \frac{1}{e^x + 1}$.

41. Given $y = x^2 e^x \cos x$, find dy .
